Crofton and Douglas has always been characterised by beautiful, lucid writing and this continues to be an outstanding feature, supported by many attractively presented figures, radiographs, and line drawings. Reading this book is a real pleasure. A second major strength is the very balanced perspective it provides. The authors are skilled at separating the genuinely important from more transient fashionable fads and the writing is proportional to the requirements of the reader and the importance of the topic. The book is clearly focused on the needs of patients and the need to prevent disease Bronchiectasis was considered a morbid disease with a high mortality rate from respiratory failure and cor pulmonale [4]. The clinical picture varies greatly and may involve repeated respiratory infections alternating with asymptomatic periods or with chronic production of sputum. Bronchiectasis should be suspected especially when there has been no exposure to tobacco smoke [5]. Health care planners, for example, are faced with a dramatic increase in tobacco use and must establish priorities for the allocation of limited resources. Respiratory stimulation was elicited from this region by increased Pco 2 and (H⁺), nicotine, and acetylcholine; and respiratory depression by procaine, NaCN, lobeline, cold CSF, decreased Pco 2 and (H⁺). CSF made acid by high (Cl⁻) at constant Pco 2 moved the entire CO 2 response curve to the left and was a more effective stimulus than normal CSF. When one reviews a medical book, it is rare that the reading is exciting, interesting, and thoroughly absorbing.
